1

Communication Protocol for Achieving Use Cases of Cooperative Driving Automation

# FY 2022 Results Report Overview

Oki Electric Industry Co., Ltd. NEC Corporation

March 2023

# Scope

## Overview

In this study, based on the result of feasibility studies of communication technologies such as requirements for wireless communication technology applied to the cooperative automated driving Use cases, and on the output of Roadmap development, which defines concrete requirements for each Use cases and wireless communication technology including expectation to communication technologies to be developed for the future, the wireless device specification was prepared mentioning communication protocols required for the implementation of V2X system with radio wave in 5.9 GHz band (hereafter V2X system in 5.9 GHz band) in order to advance solving related issues and study.

#### Actions and Achievements

• The activities shown below were carried out with medium and long term perspectives in mind.

### a) International standardization trends research

We researched and analyzed standardization and institutionalization trends related to the V2X system in 5.9GHz band communication protocol, message sets, as well as relevant communication specifications in countries and regions including the U.S., Europe and China.

## b) Research aimed at developing communication protocol proposals

The V2X system with 5.9 GHz band communication requirements for the technological research of communication protocols was studied based on the communication requirements and message sets discussed through ITS Infocommunication Forum, as well as on the result of the Roadmap development.

## c) Designing communication protocol proposals

Based on the evaluation results of the communication simulation, we designed the communication protocol for the V2X system in the 5.9 GHz band, which was concluded as communication protocol proposal mentioning communication procedures and protocol stack, along with message sets.

### d) Proposing wireless device specifications

Taking into account functions required for practical implementation and cooperation with existing wireless systems, we developed a specification for on-board unit and roadside unit using V2X system in 5.9 GHz band then clarified issues for implementation and counter measures to solve the issues.

Standardization trends related to communication specifications by standardization bodies in Europe, US, and China regarding communication protocols.

[Standardization organization specifications, etc. in regions subject to study]

### Result 1/2

- Consideration and standardization of new services are progressing in Europe and US
  - In addition to services that use basic messages such as BSM and CAM/DENM, messages that contribute to the safety of pedestrians, etc. (VRUs) are also standardized in SAE and ETSI.
  - As cooperative recognition, standardization of messages for sharing sensing data (CPS/CPM) and messages for vehicle driving adjustment is also progressing.
  - It is necessary to continue to investigate trends related to such services and consider the necessity of such services.
- Standardization of communication and control has been established
  - Standards for LTE-V2X and DSRC (802.11p) have been developed, but the use of new communications such as NR-V2X and 802.11bd is still under development, and it is necessary to grasp trends such as standardization in the future.
  - In addition, due to changes in needs due to new services (for example, an increase in communication traffic due to the application of VRUs to a VRU, an increase in communication volume due to data sharing, etc.), it is expected that the study and standardization of control methods will continue, and it is necessary to pay close attention to such trends.
- Comparison with SIP use cases and message specifications (shown on the next page)
  - There is no significant difference in the concept of use case classification and message specification.

## Result 2/2

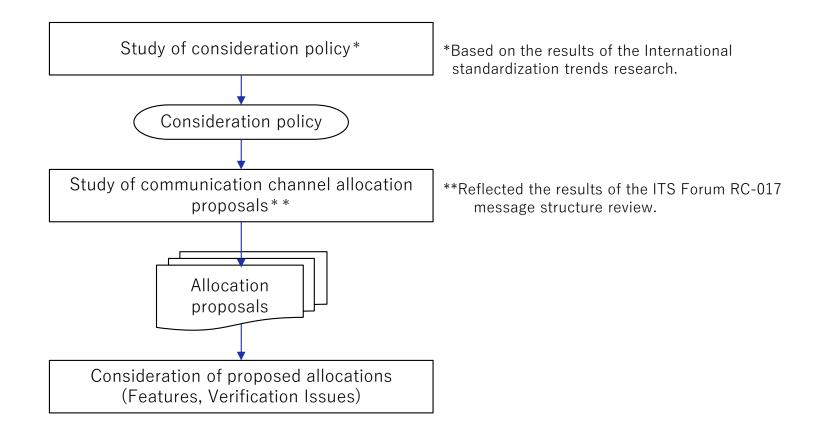

- Comparison with SIP use cases and message specifications
  - However, messages related to negotiation are under consideration in Europe and the United States, and additional studies are required regarding future communication specifications.

1) Communication channel allocation

- Communication channel allocation
  - Study procedures

#### Communication channel allocation

- Basic Concept
  - Since V2I use cases and V2V use cases are different situations, in principle, use different channels.
  - Since negotiation involve a large number of exchanges (sometimes variable), in principle, a channel different from the broadcast is used.
  - Since emergency events (sudden braking, etc.) that occur in the vehicle should be communicated reliably, in principle, use a different channel.

		V2I	V2V
Broadcast	Continuo us	Vehicle receives broadcast from roadside units a-1-1. Merging assistance by preliminary acceleration and deceleration a-1-2. Merging assistance by targeting the gap on the main lane b-1-1. Driving assistance by using traffic signal information (V2I) c-2-2. Driving assistance based on intersection information (V2I) Group A	Vehicle broadcasts every time position, speed, etc. c-2-1. Driving assistance based on intersection information (V2V) e-1. Driving assistance based on emergency vehicle information Group C
cast	Emer gency		Vehicle broadcasts alert warning when taking sudden hard breaking c-1. Collision avoidance assistance when a vehicle ahead stops or decelerates suddenly c-3. Collision avoidance assistance by using hazard information Group D
Negotiation		Automated vehicle negotiates for merging with using V2I communication a-1-3. Cooperative merging assistance with vehicles on the main lane by roadside control	Automated vehicle negotiates for merging using V2V communication a-1-4. Merging assistance based on negotiations between vehicles a-2. Lane change assistance when the traffic is heavy a-3. Entry assistance from non-priority roads to priority roads during traffic congestion

#### Communication channel allocation

#### Result

- > The proposal is shown in the table on the following page.
- Points for future continuation
  - Results of additional study of communication requirements (cycle, quality, etc.) taking into account the simultaneous occurrence of multiple use cases and cooperation between use cases, etc.
  - Communication control specifications (transmission control, priority)
  - How to realize 5.9 GHz band multichannel in radios
  - Shared with 700MHz band intelligent transportation system

#### Future study procedures

2) Communication congestion control methods at upper layers

Communication congestion control methods at upper layers

Study procedures

### Communication congestion control methods at upper layers

- **Result** 1/2
  - Referring to the specifications of the United States (SAE) and the Europe (ETSI), we devised a communication congestion control method at the upper layer as an ideal state.
  - The next page shows an image of realizing communication congestion control based on case studies for each functional requirement.

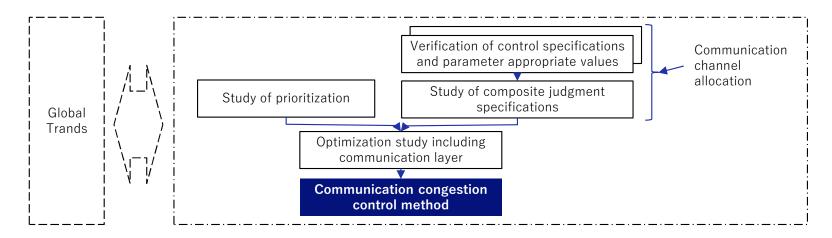

Specifications		Proposed	SAE(BSM)	ETSI(CAM)
Transmission timing	Vehicle information	0	N/A	0
control	Critical events	0	0	N/A
	Driving environment	0	N/A	N/A
	Surrounding vehicle density	0	0	N/A
	Surrounding communication status	Ο	N/A	$\Delta(DRSC \text{ only})$
Priority control		0	0	0
Transmit Power contr	ol	(Future consideration)	$\Delta$ (DRSC only)	N/A

 ${\rm O}$  : Full function,  ${\rm \bigtriangleup}$  : Limited function

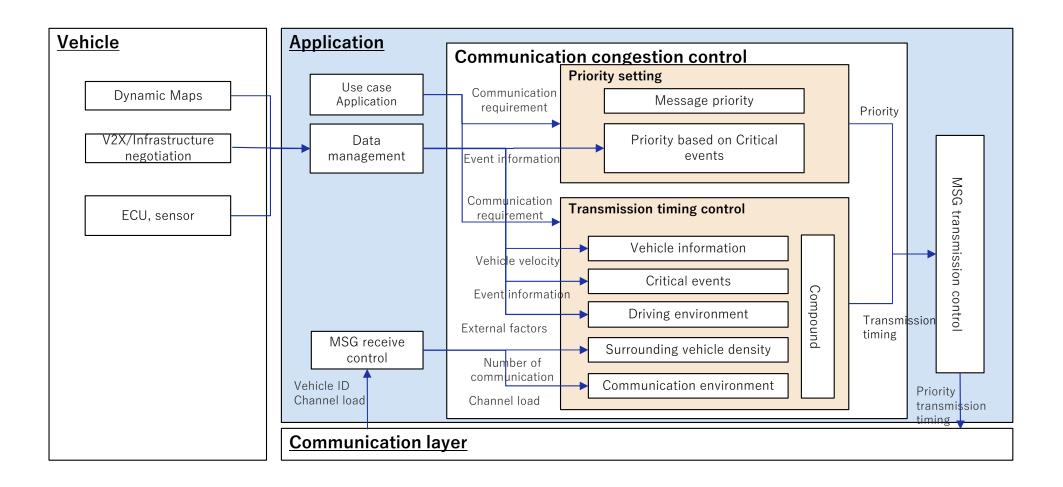

### Communication congestion control methods at upper layers

- Result 2/2
  - Through verification of the transmission timing judgment requirements, it was confirmed that the communication volume can be suppressed under the following vehicle density condition for each judgment requirement.
    - 20km/h~70km/h, distance between vehicles per second
  - Matters requiring further consideration
    - Verification of control specifications and parameter appropriate values through various case studies.
    - Study of composite decision specification for multiple transmission timing control requirements.
    - Overall optimization study including communication control at the communication layer.

#### Future study procedures

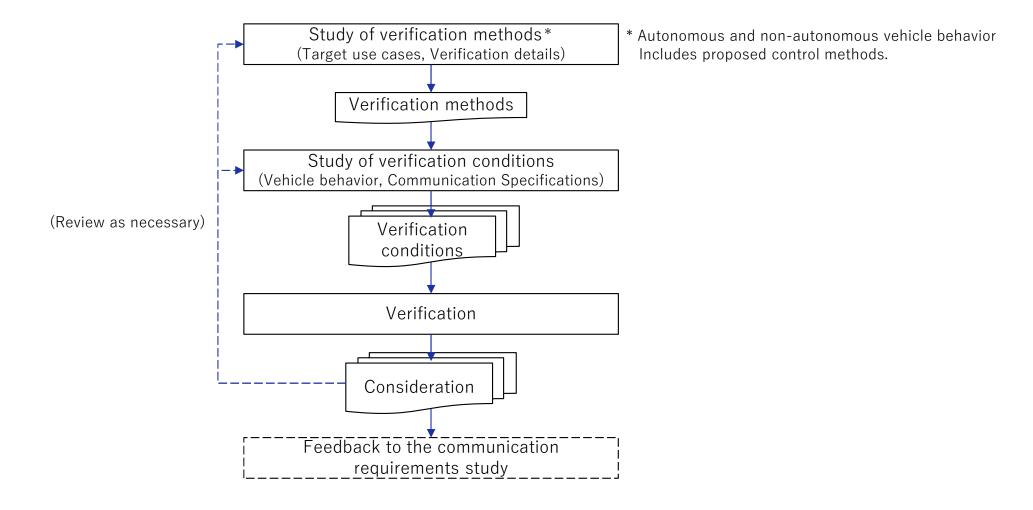

Communication congestion control realization image(Function block)

3) Traffic flow simulation-based effectiveness evaluation

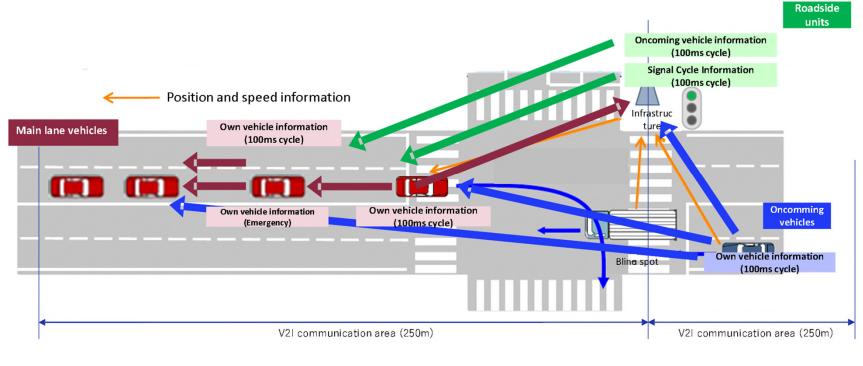

- Traffic flow simulation-based effectiveness evaluation
  - Study procedures

Traffic flow simulation-based effectiveness evaluation

### Use cases to validate

- c-1 : Collision avoidance assistance when a vehicle ahead stops or decelerates suddenly
- Notification from the leading vehicle to the following vehicle encourages early deceleration. At that time, the vehicle behavior (deceleration, jerk) of the following vehicle was evaluated.

Example of communication around an intersection

Traffic flow simulation-based effectiveness evaluation

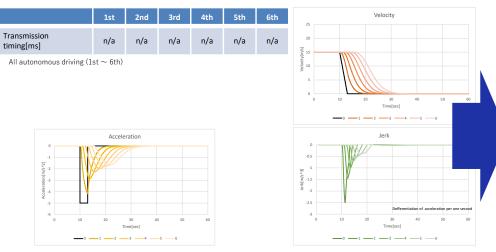

#### Result

- 5.9GHz band V2X System Effects
  - •In addition to "deceleration" as safety, evaluation was conducted from the viewpoint of "jerk" as riding comfort.
  - •By detecting the sudden deceleration of the preceding vehicle by communication and the following vehicle preliminarily decelerating, the following vehicle has the effect of mitigating the peak of "deceleration" and stopping safely. The "jerk" peak is reduced, which has the effect of reducing the anxiety felt by occupants.
  - •In the comparison with and without communication, there was a more marked difference in "jerk" than in "deceleration".
- Effects of differences in communication specifications (reception timing)
  - •The difference in message reception timing (several hundred ms) did not have a significant effect on vehicle behavior.
  - •In the assumed delay range of the reception timing( $100 \sim 500$ ms), when the delay increases to 500 ms, deceleration propagation occurs due to following the preceding vehicle. Therefore, the vehicle immediately after the leading vehicle has a reduced effect of preliminary deceleration.
  - •After the second unit, no change due to differences in reception timing is observed.
  - Since it takes several seconds to propagate the deceleration of the preceding vehicle in the case without information, it is considered that even a delay of up to 500ms can be performed preliminarily deceleration sufficiently early.

#### Traffic flow simulation-based effectiveness evaluation

- Example of validation results (No communication / With communication)
  - "With communication" achieved a gradual deceleration, and the effect of communication was confirmed

#### [Case0 : No communication]

#### [Case1 : With communication]

and the curve becomes smoother. (Improvement)

1) Developing communication protocol proposals

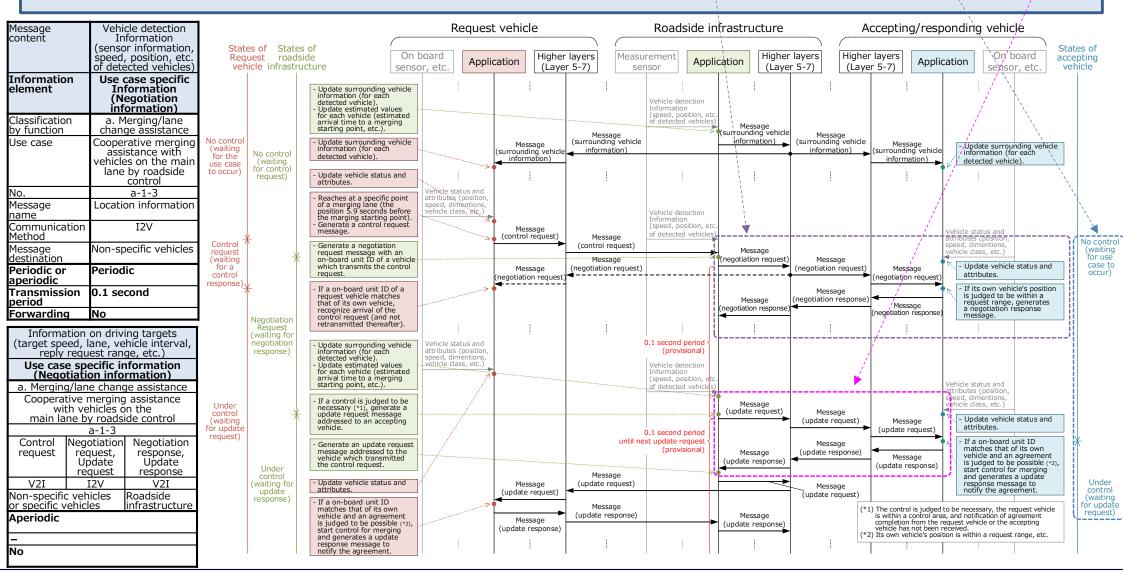

### 1) Developing communication protocol proposals Summary

- Based on communication scenarios for SIP use cases (ITS FORUM RC-017), communication protocol proposals in 5.9 GHz band were developed, and protocol stacks, communication control flow and communication specifications (function, behavior, interface, etc.) were compiled as outline proposals.
- New functions (destination identification, request/response processing) for control/agreement use cases were added after studying the feasibility of SIP use cases based on European and U.S. specifications. As similar use cases are being standardized in other countries, confirmation of future trends is needed.
- Based on the assumption that security services similar to those in the European and U.S. specifications (electronic signature method) would be provided, interfaces and procedures between layers were studied and compiled. Detailed specifications of the security services need to be further discussed.
- A desk study of the developed communication protocol proposals was conducted. By detailing message sequences and organizing the relationship between applications, protocol stacks and information providers, it was confirmed that there were no inconsistencies with the communication scenarios.
- Proposed ways to cooperation with 700 MHz band ITS was organized in a way that does not change the existing protocol stacks. Based on SIP roadmap of V2X communication methods for cooperative driving automation and a technology adoption situation, it is necessary to study the channel allocation method including 700 MHz and 5.9 GHz bands for each SIP use case in the future.
- Future issues include:
  - Review of this study reflecting the communication scenarios to be revised and international trends.
  - Study of interface specifications with non-communication functions (control systems, etc.).
  - Study of detailed procedures including state transitions, exception handling, etc.

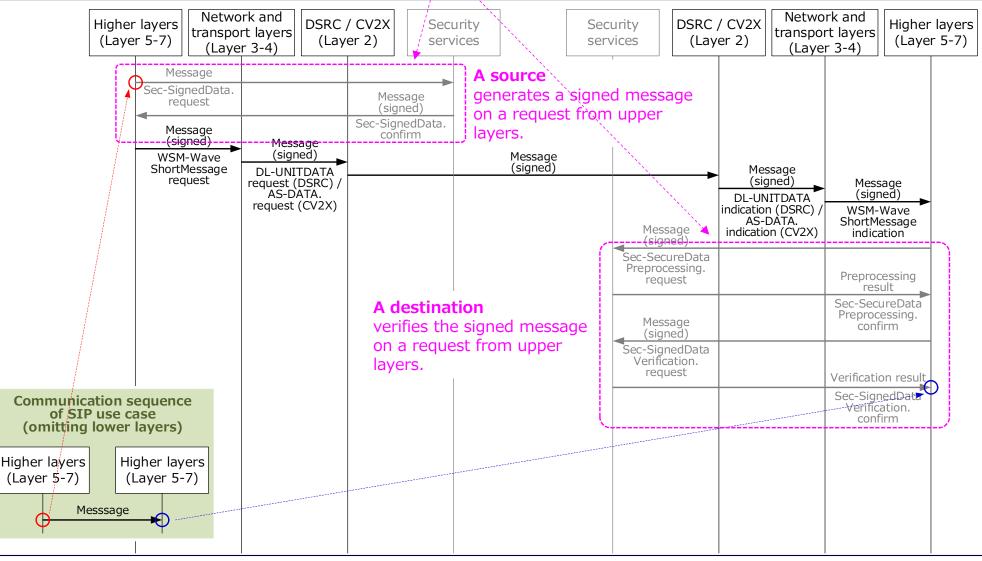

Layers	Main specifications	Notes
Application	- Destination identification, request/response processing (for control/agreement use cases) - Transmission control (Priority setting, transmission timing control)	Add functions required by control/agreements to European and U.S. specifications.
Higher layers (Layer 5-7)	I- Generate vehicle basic information and send periodically. I- Retransmit hazard information periodically. (*)	Same as European specifications. (If U.S. specifications are applied as an alternative, (*) is handled by the application.)
Network and transport layers (Layer 3-4)	I- Broadcast communication (destination unspecified)	Same as U.S. specifications. (As an alternative, it is possible to apply European specifications.)
—	Channel allocation	Assume static allocation.
Physical and data link layers (Layer 1-2)	Base on Guideline for experiments of communications system for use cases of automated driving on expressways (ITS FORUM RC-015).	Same as European and U.S. specifications.

#### Summary of communication protocol proposals

- 1) Developing communication protocol proposals **Example of desk study** - Application to communication scenarios for SIP use cases -
- Add new functions for control/agreement use cases. (<u>Destination identification, request/response processing</u>)
   Further study of detailed specifications is needed. (<u>Destination identification method, state transition</u>, etc.)
   Future confirmation of overseas standardization trends is also needed.

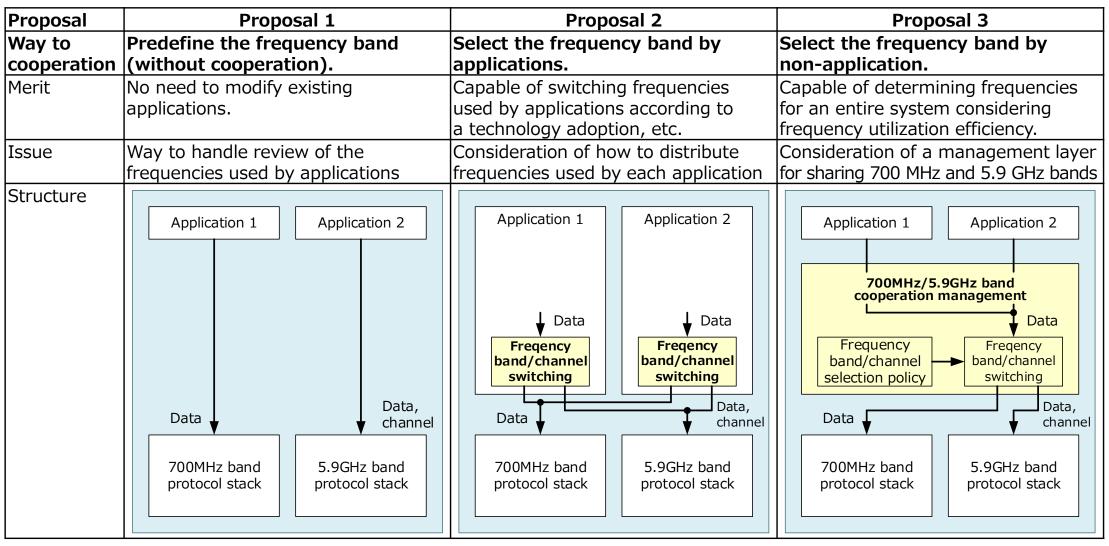

- 1) Developing communication protocol proposals Example of desk study - Procedure between layers -
- Based on the assumption that security services similar to those in the European and U.S. specifications (electronic signature method) would be provided, procedures between layers were studied and organized.
   Detailed specifications of the security services need to be further discussed.
  - \* In this study, message sizes added by security services (overhead) is reflected in the communication simulation.

### 1) Developing communication protocol proposals **Proposed ways to cooperation with 700 MHz band ITS**

- Propose proposals in which protocol stacks (layer 7 or lower) for each frequency band exist side by side and applications choose between them.
- Based on SIP roadmap and a technology adoption situation, it is necessary to study the channel allocation method including 700 MHz and 5.9 GHz bands for each SIP use case in the future.

2) Developing a message set proposal

# c) Designing communication protocol proposals <sup>30</sup>

# 2) Developing a message set proposal **Summary**

- Regarding message structure of SIP use cases, based on the results of the study by ITS Info-communications Forum (ITS FORUM RC-017), information elements, the use cases that use them and their size were organized considering commonality among the message used in each use case.
- By conducting this study using the above organized results as preconditions for 1) and 3), consistency with the channel allocation and the communication protocol proposals was confirmed.
- Based on the developed communication protocol proposals, a study of information elements multiplexing was conducted. It was confirmed that combining multiple information from different destinations or use cases into a single packet and reducing the security overhead can be expected to reduce the communications traffic.
- Future issues include:
  - Review of this study reflecting the message structure to be revised.
  - Study and evaluation of detailed procedures for the information elements multiplexing.

#### Organized result of a message set proposal (Summary)

### 2) Developing a message set proposal Case studies of information elements multiplexing method

- **Consider reducing communications traffic by combining multiple information** from different destinations or use cases into a single packet and reducing security (electronic signatures) overhead.
- Studies were conducted for roadside infrastructures and vehicles, respectively (and the results were reflected in communication simulation evaluation).
  - When **roadside infrastructures** send negotiation/update requests to multiple vehicles for UC a-1-3 (cooperative merging assistance with vehicles on the main lane by roadside control)
  - When vehicles send messages of multiple use cases on the same channel

3) Simulation-based communication performance evaluation

### 3) Simulation-based communication performance evaluation Summary

- Under mixed environments of SIP use cases (and interference sources) at an expressway merging section and a general road intersection, communication performance was evaluated using CV2X (LTE V2X) when multiple channels were allocated within a 30 MHz bandwidth and messages (information elements) of the multiple use cases were multiplexed.
- A comparison of multiple channel allocation proposals showed that communication quality was generally better when V2V use cases were assigned to one channel than when they were assigned to two channels within a 20 MHz bandwidth. When information elements on the same channel is multiplexed and combined into a single packet, a smaller number of channels means fewer packets per bandwidth, which can reduce transmission frequency and security overhead (communications traffic) and is considered effective in reducing intra- and inter-channel interference.
- Compared to single channel cases (up to 20 MHz bandwidth), the result did not necessarily show an improvement in the communication guality. In cases where vehicles transmissions are distributed across the multiple channels due to the multiple channel allocation, this is considered to be due to inability to multiplex information elements across the different channels, which increases the number of packets per bandwidth and thus increases intra- and inter-channel interference.
- To verify effectiveness of a communication control method, communication performance was evaluated when transmission periods of vehicles were extended. It was confirmed that communication guality could be improved in situations where the communication was congested and a required PAR could not be achieved.
- Based on the evaluation results, to improve communication quality in situations where multiple use cases occur simultaneously and communications traffic is high, it is considered effective to transmit information elements together in a single packet on a small number of channels (with less communications traffic and lower transmission frequency by decreasing the number of packets per bandwidth) and to control transmission periods and the number of retransmission according to congestion conditions (and reduce transmission frequency during congestion).

#### Future issues include:

- Comparison of single channel and multi-channel performance in the same bandwidth. (For example, for NR V2X, is it better to use one channel with a bandwidth of 30 MHz or to divide the bandwidth into two or more channels?)
- Verification of the effectiveness of channel allocation methods other than methods of allocating channels on a per-service basis. (For example, when multiplexing information elements, channel utilization efficiency may be improved if a channel is divided by source rather than by use case. Such as, dividing between transmissions of roadside infrastructures (I2V) and those of vehicles (V2I and V2V).)
- Detailed evaluation of communication control methods considering time variation of the transmission periods, priority, etc.

#### For the expressway merging section

(\*1) Its data size is for 50 km/h and 1 second vehicle interval (for 100 km/h and 2 seconds vehicle interval, 708 bytes).

(\*2) Its data size is for 50 km/h and 1 second vehicle interval (for 100 km/h and 2 seconds vehicle interval, 718 (x 2) bytes if multiplexing information elements and 298 (x 16) bytes if not multiplexing them). The notation "718 (x 4)" indicates that 718 bytes are transmitted 4 times.

# c) Designing communication protocol proposals <sup>35</sup>

# 3) Simulation-based communication performance evaluation **Example of simulation results**

A comparison of channel allocation methods showed:
 Communication quality was generally better when V2V use cases were assigned to one channel (Proposal 6) than when they were assigned to two channels (Proposal 1) within a 20 MHz bandwidth.
 -> Because information elements on the same channel was multiplexed, a smaller number of channels means fewer packets per bandwidth, reducing transmission frequency and security overhead (communications traffic).
 Compared to single channel cases (up to 20 MHz bandwidth), the result did not necessarily show an improvement in the communication quality.
 -> When vehicles transmissions are distributed across the multiple channels due to the multiple channel allocation, information elements can not be multiplexed across the different channels, increasing the number of packets per bandwidth.
 Verification of effectiveness of a communication control method (when transmission periods of vehicles were extended) showed:

It was confirmed that <u>communication quality could be improved</u> in situations where the communication was congested and a required PAR could not be achieved.

# d) Proposing wireless device specifications <sup>39</sup>

- 1) Examination of wireless device specifications Example of results: 2. V2X system overview - Equipment configuration -
- Based on the functions and operations related to channel allocation in the communication protocol proposal (assumed to have the same number of radio sections (Layer 2 or lower) as the number of allocated channels), organize the equipment configuration that supports multi-channels.
  - It is necessary to have a radio sections or a radio sections + communication control sections (L3 to L7) for the number of allocated channels

## d) Proposing wireless device specifications 40

- 1) Examination of wireless device specifications Example of results: 2. V2X system overview - Equipment configuration -
- Equipment configuration that takes into the method of cooperation with the existing ITS:Proposal2 Introduced 5.9GHz band wireless device
  - Corresponds to proposal 2 for cooperation with 700 MHz band ITS in c)
  - Each application can select the frequency used depending on the situation of spread because one application is configured to be able to access communication layers of existing ITS and 5.9GHz band.

- 1) Examination of wireless device specifications Summary
- Regarding the system configuration, device configuration, functions/characteristics/interfaces, we compiled a proposal for wireless device specifications by organizing the specifications corresponding to the communication protocol proposal, etc.
- Based on the SIP roadmap of V2X communication methods, the equipment configuration proposal was organized by considering the method of cooperation with the existing ITS radio equipment for each period of introduction and post-introduction of the 5.9 GHz band wireless device.
- Future issues include:
  - Continuous study of multi-channel support methods by quantitative evaluation
  - Consideration of specifications for items whose priority has been lowered
    - Hardware specifications for interfaces
    - Functions other than communication (Fault detection, power supply, etc.)
  - Detailed examination of interface requirements with the vehicle

# d) Proposing wireless device specifications

2) FOTs on test courses, etc.

- 2) FOTs on test courses, etc. **Content of implementation**
- Conduct FOTs (Field Operational Tests) on a test course under conditions where multiple use cases coexist
  - Conducted communication performance evaluation when using multiple channels and 20MHz bandwidth, and verified the effect of channel allocation
  - Uses CV2X (LTE V2X (PC5)) communication equipment

# d) Proposing wireless device specifications

3) Clarification of issues and its solutions for implementation

# 3) Clarification of issues and its solutions for implementation

Issues	Content	Solutions
	It is necessary to decide whether to specify the details of the configuration of the multi-channel support method in the wireless device specifications.	Quantitatively evaluate performance requirements such as throughput, costs, implementation conditions, etc., and clarify the gaps in the system requirements for each configuration.
Updating wireless device specifications based on how to link with existing radio systems	If you need functions, interfaces, etc. for cooperation, it is necessary to replace the equipment, especially the 700MHz band wireless device that has been introduced in advance.	Clarify the performance and functional requirements necessary for coordination according to the channel allocation study results. Based on the results, we will implement functions for cooperation in the 700MHz band wireless device prior to the introduction of the 5.9GHz band.
Detailed examination of interface requirements with the vehicle	As a method of obtaining own vehicle information, it is assumed that the information is passed through the control device on the vehicle side. It is necessary to decide the applicable interface specifications in the future.	While considering flexibility and scalability for future additions and changes to UC, clarify requirements such as message information acquisition frequency and delay based on service requirements and service feasibility. Based on the results, we will discuss and consider with related organizations.
Detailed determination of security specifications	Security specifications for domestic V2X systems have not yet been decided.	Considering trends in Europe and the United States, IEEE1609.2 (currently being revised) is considered to be one of the options for V2X security. It is necessary to obtain a consensus among users and stakeholders on how to apply it.
Promotion of standardization of upper layers of communication	Establish a forum for industry-academia- government to examine the details of the standard specifications for the upper layer of communication. In addition, standardization strategies should be considered.	Strengthen cooperation with organizations such as users and providers, who are stakeholders regarding standardization, and determine standardization strategies and objectives. Furthermore, we will select the target standardization organization for the draft standardization and promote standardization.

This report documents the results of Cross-ministerial Strategic Innovation Promotion Program (SIP) 2nd Phase, Automated Driving for Universal Services (SIP-adus, NEDO management number: JPNP18012) that was implemented by the Cabinet Office and was served by the New Energy and Industrial Technology Development Organization (NEDO) as a secretariat.
